## Introduction

## Scope

The State Board of Administration of Florida (SBA) engaged the Mercer Sentinel® Group (Mercer Sentinel) to benchmark its thirty-seven global and international investment managers' foreign exchange (FX) execution. These thirty-seven managers represent those strategies managed as separate accounts, each of which is custodied with BNY Mellon. The analysis does not consider SBA's foreign currency exposure through its commingled investment accounts, which represented approximately 22% (as of 30 June 2010) of SBA's total international and global equity assets. This study examines data for the 59-month period 1 July 2005 to 31 May 2010. In this analysis, Mercer Sentinel estimates SBA's total FX execution costs, assesses overall trading patterns, and identifies potential issues for further consideration and discussion.

#### Sources

SBA's custodian, BNY Mellon, provided the FX execution records. Mercer Sentinel has checked the data, but we cannot verify the data accuracy or completeness, as we have no means for verifying what should have been provided. The analysis in this report presumes the data is correct.

BNY Mellon did not provide time-stamped transaction data. Absent time-stamped data, benchmarking relies on evaluating execution performance based on the intra-day trading range of the currencies traded, the price at which each trade was executed, and the volume of each trade executed. We used Bloomberg as the primary market data source. Bloomberg is widely accepted in the foreign exchange market as an accurate and reliable pricing information source. Within Bloomberg, we use the BGN FX rate, which has been algorithmically filtered, as opposed to the composite FX rate (ALLQ), which is an unfiltered composite from all contributing dealers. In our experience and estimation, approximately 2% of valid trades fall outside the day's range as reported by BGN. A significant variance greater than 2% of transactions would indicate a potential problem.

## Methodology

In April 2007, Mercer Sentinel acquired rights to software and methodologies originally developed by Record Currency Management Limited, a UK-based currency manager. Since then, Mercer Sentinel has continued to advance the tools and analytical approach supporting this intellectual capital.

As BNY Mellon did not provide time-stamped trade data, our analysis evaluates individual trades against the mid-price for the day, and then uses statistical principles to aggregate those individual results into meaningful cumulative results. A fundamental assumption underlying our analysis methodology is that foreign currency trades are normally distributed around the mid-price for the day. "Mid-price" is defined as the average of the recorded high and low prices.

Mercer Sentinel analyzes trades according to trade size, direction (buys and sells), currency pairs, and SBA's execution sources or contract types. SBA's data has sufficient observations to draw statistically significant conclusions for all commonly used ways of assessing the data. Some exotic currency pairs lack meaningful sample sizes; however, these pairs do not comprise a significant portion of SBA's trading activity.

#### Trade size

Mercer Sentinel allocates trades into three size groups, as shown in Table 1.1.

Table 1.1 Trade sizes

| Category   | Trade value            |
|------------|------------------------|
| Market     | \$500,000 or greater   |
| Non-market | \$150,000 to \$500,000 |
| Micro      | Less than \$150,000    |

# Trading direction

In this analysis, activity vis-à-vis the US dollar determines trade direction. Buys are trades purchasing US dollars and sell trades are the opposite. Cross trades occur when the transaction does not involve US dollars, such as a Euro to British pound sterling trade. Mercer Sentinel evaluates cross trades separately from buys and sells. Where we identify notable items with cross trades, we highlight them separately.

## **Currency pairs**

Mercer Sentinel classifies the primary global currencies as reserve currencies, and transactions in those currencies as reserve trades. The global reserve currencies are those held in significant quantities by many governments and institutions as part of their foreign exchange reserves. The following are reserve currencies:

Mercer 4

\_

<sup>&</sup>lt;sup>1</sup> Appendix A provides greater detail on our execution analysis methodology.

- Euro (EUR)
- US dollar (USD)
- British pound sterling (GBP)
- Japanese yen (JPY)
- Canadian dollar (CAD)
- Swiss franc (CHF)

All other currencies are classified as secondary. Any trade involving a reserve currency and a secondary currency is put into the secondary currency category.

## Settlement period

Mercer Sentinel analyzes and reports spot and forward FX executions separately. Based on market convention, Mercer Sentinel considers FX executions settling within three trading days of the execution date as spot executions, and those settling four days or later as forward executions. We analyze spot executions against the day range on trade date and forward executions against interpolated near-term contracts. For example, we interpolate a ten-day forward contract using a one-week and a two-week standard, near-term contract.

## Contract type

SBA's investment managers instruct FX execution through internal BNY Mellon treasury desks or external trading desks. Specifically, the data has seven contract types that we analyzed:

Internal contract types:

#### Non-negotiated

- CIBC Mellon (C)
- London treasury (N)
- Pittsburgh treasury (T)
- Sub-custodian (I)

#### External contract types:

#### Negotiated

External broker (E)

# Negotiated

- London treasury (L)
- Pittsburgh treasury (X)

# Graphic presentation

Mercer Sentinel presents the activity within various categories by plotting execution results on a chart. We show the investment managers' actual execution results using dark blue bars. For each data sample or category, we show the investment managers' activity twice: once by number of executions and once by value of executions.

The X-axis represents the percentage deviation from the day's average price relative to that day's posted trading range. Observations greater than 100% or less than -100% on the X-axis represent trades executed outside the day's posted trading range. We expect for any dealer market a small portion of trades to fall outside the day's posted range, as dealers may not post all executions or the data provider may remove various executions for validity reasons.

The light blue line presents a normal distribution curve, representing our expectation of results for each category. We assume a constant variance across all categories, allowing us to provide an approximate depiction of the expected outcome distribution of the underlying data for that specific sample. Therefore, this normal distribution curve does not necessarily represent market nuances among different categories, such as market and micro sized executions or among different currency pairs.

2

# Summary

Over the examination period, SBA realized total excess costs of about \$22.1 million, or about 3.5 basis points, from spot and forward FX executions. Spot executions, which represent about 80% of traded value, accounted for \$21.6 million of the total expense. Forward execution costs over the five-year period were modest, incurring only \$519,000 of expense, or less than one-half basis point of traded value. Given that our analytical process allows for a 'normal' prevailing spread in each currency pair, in our opinion, the forward results are acceptable but the spot results are more costly than warranted.

SBA's total spot and forward FX cost results are better than or consistent with observations for most other large institutional investors in our experience. However, there are areas within SBA's FX program that have potential for worthwhile improvement. For example, we believe SBA may be able to achieve better prospective results for its non-negotiated executions by expanding its investment manager supervision and through negotiation with BNY Mellon. Although SBA's non-negotiated execution results are consistent with market practices we have observed in the past, these practices are opaque and expensive.

Spot FX transactions executed with SBA's custodian, BNY Mellon, had excess costs of about \$27.7 million, or about 10.4 basis points. In contrast, spot transactions executed away from BNY Mellon had an excess benefit of about \$6.1 million, or 2.6 basis points. Forward FX executions by BNY Mellon had excess costs of about \$928,000, or 4.4 basis points; forward FX execution by third parties had excess benefit of about \$408,000, or 0.4 basis points. We recommend that SBA review these results with BNY Mellon. While the external spot and forward executions were more than satisfactory, the standing-instruction internal executions

were expensive. In particular, the vast majority of the excess cost (\$26.8 million, or 25.8 basis points) is associated with internal, non-negotiated executions (contracts N and T).

BNY Mellon executed (through internal negotiated and non-negotiated contract types) approximately 9% of total spot trades (by number) outside the day's traded range and 8% of total forward trades (by number) outside the day's traded range. Executing trades at prices outside the day's trading range can indicate poor execution controls. Mercer Sentinel recommends SBA review these out-of-range executions with BNY Mellon. The continued presence of outlier executions, which is consistent for each year's results, represents a persistent problematic pattern and may indicate loose execution controls.

Table 2.1 Aggregate execution profile - spot vs. forward

|         | Trades                   |                          |       | 6 disadvantag | eous by value  | Excess (cost) / benefit |             |                           |
|---------|--------------------------|--------------------------|-------|---------------|----------------|-------------------------|-------------|---------------------------|
|         | Volume in #<br>of trades | Volume in USD<br>(000's) | Total | Market        | Non-<br>market | Micro                   | USD (000's) | Bps of<br>traded<br>value |
| Spot    | 96,308                   | 50,377,952               | 54%   | 52%           | 61%            | 66%                     | (21,578)    | (4.3)                     |
| Forward | 5,910                    | 12,789,201               | 48%   | 48%           | 57%            | 59%                     | (519)       | (0.4)                     |
| Total   | 102,218                  | 63,167,153               | 53%   | 51%           | 60%            | <b>65</b> %             | (22,098)    | (3.5)                     |

External spot executions, which are those executed away from BNY Mellon, represented about 26% of total spot executions by number and about 47% by traded volume. SBA's investment managers used external brokers (by number of total executions) less than half the time.<sup>2</sup> For forwards, external brokers realized an excess benefit of about \$408,000, or about 0.4 basis points.

External brokers executed less than 2% of total spot trades outside the day's traded range: Table 2.2 below indicates that significant amounts of out-of-range executions are not intrinsic to FX trading.

<sup>&</sup>lt;sup>2</sup> External broker use by total number of trades: 42% (2005); 34% (2006); 30% (2007); 21% (2008); 19% (2009); 32% (2010).

Table 2.2 Internal versus external execution outside the day's range by frequency<sup>3</sup>

|                             | 2005 | 2006 | 2007 | 2008 | 2009 | 2010 |
|-----------------------------|------|------|------|------|------|------|
| Internal (C, N, T, L, X, I) | 11%  | 13%  | 10%  | 7%   | 8%   | 10%  |
| External (E)                | 2%   | 2%   | 2%   | 1%   | 3%   | 1%   |
| Total                       | 7%   | 9%   | 8%   | 6%   | 7%   | 7%   |

Table 2.3, which considers executions by contract type, shows that:

- 74% of the volume traded was competitively negotiated at rates representing a net benefit to SBA. These trades were executed via third parties or the custodian's capital markets desks.
- 5% of the volume traded was executed using BNY Mellon's sub-custodian network. Generally, these executions represented trades in "restricted" currencies that have a potential for higher costs.
- 21% of the volume traded was executed through the BNY Mellon Custody Management System on a standing instructions, non-negotiated basis. These executions are the primary source of excess costs in SBA's FX program.

Table 2.3 Aggregate spot execution by contract type

| Contract Trades |                          |                         | Excess (co | st) / benefit       | Percent of Total |                         |              |

## Contract type

FX spot transactions executed with BNY Mellon as trading broker (contract types C, I, N, T, L and X), realized an excess cost of \$27.7 million, or 10.4 basis points. In contrast, FX spot transactions executed away from BNY Mellon as trading broker realized an excess benefit of \$6.1 million, or 2.6 basis points.

With the exception of restricted currencies, SBA's investment managers can choose to execute FX trades with BNY Mellon or with any external broker. Contract types C, N and T represent non-negotiated executions, in which the investment manager accepts the custodian's discretion regarding the FX rate. Non-negotiated trades had an excess cost of 25.8 basis points, or \$26.8 million. Contract types L and X represent negotiated rates executed through the custodian's capital markets desk, in which the investment manager maintains discretion over FX rates. Negotiated rates realized an excess benefit of 0.2 basis points, or about \$270,000. Contract type I executions are non-negotiated rates that require local market derived rates due to market or government restrictions. These rates represent mostly secondary currencies and most of SBA's restricted currencies. Overall, BNY Mellon's sub-custodians executed trades as expected for secondary currencies, costing 4.9 basis points, or about \$1.2 million. We consider all external brokers as having negotiated rates, regardless of whether the investment manager actively negotiates or passively accepts the external rates offered. Overall, external brokers executed trades with an excess benefit of 2.6 basis points, or \$6.1 million.

SBA's investment managers used contract type T, or non-negotiated executions with BNY Mellon's Pittsburgh trading desk, more frequently than any other contract type, which realized 25.7 basis points of excess cost. Two-thirds of contract type T executions were micro-sized trades, and are likely auto-repatriation actions. Auto-repatriation is the process whereby dividends and interest payments are converted automatically to the base currency, US dollars, according to standing instructions. SBA should speak with BNY Mellon about its auto-repatriation controls; further, SBA may wish to require BNY Mellon to price auto-repatriation executions against a standard market-fixing rate.

Table 2.4 Aggregate execution profile by contract type

| Contract       | Trades                   |                          | % disadvantageous by value |        |            |       | Excess (cost) / benefit |                           |
|----------------|--------------------------|--------------------------|----------------------------|--------|------------|-------|-------------------------|---------------------------|

## Trading period

SBA's investment managers executed spot trades at an overall cost. Trading years 2008 and 2009 represent more than half of the total executions for all years reviewed and had the highest overall costs to SBA. In these years, SBA investment managers used BNY Mellon to execute 79% and 81% of all spot executions by number – the highest internal rate of all years reviewed.

Table 2.5 Aggregate spot execution profile by year

| Year <sup>4</sup> | Т                        | rades                    | %     | disadvantag | Excess (cost) / benefit |       |             |                           |

## Trade size

SBA's investment managers executed approximately \$50.4 billion in spot executions during the review period at an excess cost of 4.3 basis points, which we regard as more costly than warranted. Market-sized executions, which represent \$41.6 billion, or about 83% of total volume traded but only 22% by number, realized an excess cost of \$10.7 million, or 2.6 basis points. Eight-percent of market trades were outside the day's trading range; BNY Mellon internal contract types accounted for about 92% of the 1,600+ trades outside the day's range for market-sized trades.

<sup>&</sup>lt;sup>4</sup> Years 2005 and 2010 are partial years; specifically, 2005 covers from 1 July 2005 and 2010 covers until 31 May 2010.

Micro-trades, which accounted for \$4.1 million in total costs and 54% of spot trades by number, were problematic. While only 6% of micro-trades were outside the day's trading range, micro-trades accumulated more than 16 basis points of excess cost. BNY Mellon internal contract types accounted for about 95% of the 3,300+ trades outside the day's range for micro-sized trades. Mercer Sentinel expects BNY Mellon to execute nearly 100% of trades within the day's posted market prices, regardless of trade size.

## Currency pairs

As shown in Table 2.5, SBA received unfavorable execution in most currency pairs. Generally, currency pairs with a greater percentage of external contract types had more favorable executions. Reserve currency pairs (those executions with reserve currencies on both sides of the execution) incurred excess costs of 2.4 basis points; secondary currency pairs incurred excess costs of 8.0 basis points. These excess costs are higher than expected for both reserve and secondary currencies.

Reserve transactions had about 1% of executions outside the day's trading range, which is consistent with expectations. However, secondary currencies had about 17% of executions outside the day's trading range, which is excessive. BNY Mellon executed about 76% of secondary executions for SBA by number, and about 69% by total value traded. Based on normal industry reporting practices, we expect about 2% of trades to appear outside the day's trading range for any currency pair. Dealers do not always report execution prices or volumes, and therefore an otherwise "good" trade may appear outside a vendor's daily range. Also, data reporting providers, such as Bloomberg, algorithmically eliminate outliers so that their reported day range reflects general market trading activity. However, with such a large percentage of secondary currency trades outside the day's range, SBA may wish to discuss this execution trend with BNY Mellon, as nearly all executions should be within the day's posted trading range, regardless of currency pair.

Table 2.6 Aggregate execution profile - reserve vs. secondary currencies

|           | Т                        | rades                    | 9     | % disadvantag | Excess (cost) / benefit |       |             |                           |

| Reserve   | 60,753                   | 33,379,201               | 52%   | 50%           | 61%                     | 67%   | (8,053)     | (2.4)                     |
| Secondary | 35,555                   | 16,998,751               | 58%   | 57%           | 60%                     | 63%   | (13,525)    | (8.0)                     |
| Total     | 96,308                   | 50,377,952               | 54%   | <b>52%</b>    | 61%                     | 66%   | (21,578)    | (4.3)                     |

#### Forward executions

Forward executions realized about \$519,000, or about 0.4 basis points, of excess cost. Consistent with spot trades, internal contract types contributed excess costs: about \$928,000, or 4.4 basis points. External contract types contributed excess benefits of about \$408,000, or 0.4 basis points. External trading brokers transacted 98% of executions within the day's trading range, but only 92% of BNY Mellon's forward executions were inside the day's trading range, suggesting BNY Mellon lacks effective forward execution forward controls.

3

# Contract type analysis

## Internal trade execution

Overall, BNY Mellon's internal executions incurred approximately \$27.7 million in excess costs. Execution orders placed directly with BNY Mellon's capital markets desks ("negotiated", contract types L and X) resulted in approximately \$270,000 of excess benefit. Sub-custodian executions (contract type I) and non-negotiated executions (contract types C, N, and T) were less favorable. Subcustodian executions resulted in about \$1.2 million of excess costs. Non-negotiated executions realized about 25.8 basis points of excess cost, or about \$26.8 million.

Table 3.1 Aggregate execution profiles for BNY Mellon only

|                         | Tr                          | ades                        | % disadvantageous by value |        |                |       | Excess (cost) /<br>benefit |                           |

## Non-negotiated executions

More than two-thirds of BNY Mellon's non-negotiated executions were micro-sized trades, and are likely subject to an auto-repatriation process. Auto-repatriation is a process whereby investment managers use standing instructions to convert small amounts to a base currency automatically. Operational efficiency is a primary reason investment managers prefer auto-repatriation to convert foreign dividend or interest payments to the base currency. From the investment manager's perspective, oversight of income repatriation is an operational responsibility that may not present them an opportunity to add alpha. However, some investment managers overlook the importance of avoiding alpha erosion in the income repatriation process.

These micro-sized executions incurred 34 basis points of excess cost, or more than \$4.1 million. Six percent of these executions were outside the day's trading range, and more than 86% of all micro executions were at disadvantageous prices. BNY Mellon should execute nearly all trades within the day's range and realize little to no excess costs. SBA should discuss these results with BNY Mellon and SBA's investment managers to understand how each party oversees the process. Prospectively, SBA may wish to benchmark auto-repatriation executions.

Table 3.2 All internal, standing executions by trade size (Contract Types C, N, T)

|                                      |            |           | Non-      |           |
|--------------------------------------|------------|-----------|-----------|-----------|

| % within days range (by value)       | 84%        | 80%       | 89%       | 94%       |
| % within days range (by number)      | 92%        | 83%       | 89%       | 94%       |

## Internal contract type C

Contract type C, which represents non-negotiated executions through CIBC's treasury desk, had only two executions and was last used in 2007. Individually, contract type C does not have a sufficient number of observations to draw statistically significant conclusions. While we do not analyze contract type C executions as a group, we include them in any relevant subsets, such as "internal executions" and include them within the overall dataset analysis.

Chart 3.1 All internal contract type C trades by value

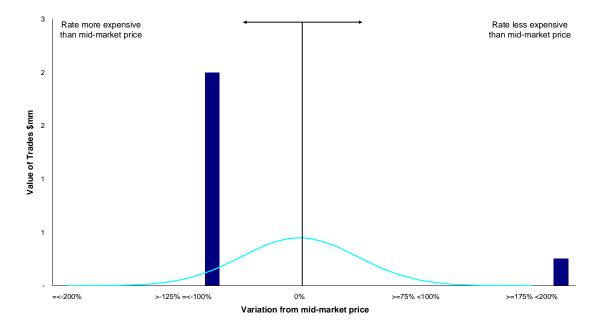

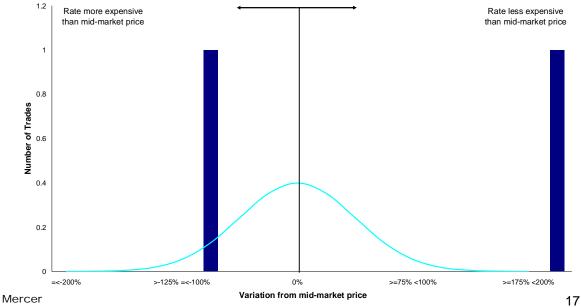

Chart 3.2 All internal contract type C trades by number

## Internal contract type N

Contract type N represents 285 non-negotiated executions with BNY Mellon's London treasury desk. Overall, the London desk realized more than \$164,000 in excess costs, which is approximately 159 basis points against traded value. About 98% of all internal, London executions were micro-sized trades, and are likely auto-repatriation. These micro-sized trades realized about 14 basis points of excess costs, and had about 5% of executions outside the day's trading range. The London treasury desk only executed three market-sized trades, which accumulated more than \$156,000 in excess costs, or 371 basis points. Regardless of trade size, the London desk's results suggest a problematic pattern, potentially through poor internal controls. BNY Mellon should explain the reason for its London desk's poor execution pattern.

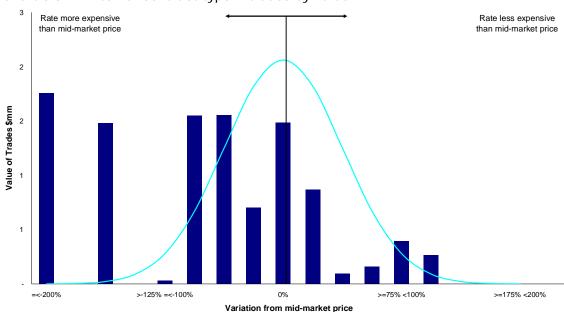

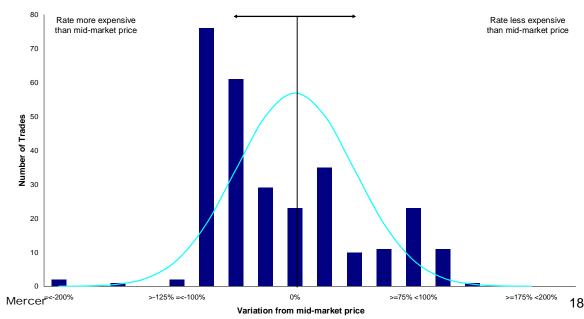

Chart 3.3 All internal contract type N trades by value

Chart 3.4 All internal contract type N trades by number

## Internal contract type T

Contract type T represents all non-negotiated executions through BNY Mellon's Pittsburgh trading desk. SBA's investment managers used this method for more than 43,000 trades and \$10.3 billion of value. While this contract is the most frequently used by number, 45.1% of all trades, it represents just 20.6% of value transacted. Overall, the Pittsburgh desk realized excess costs of more than 25 basis points, or \$26.6 million. More than 8% of all contract type T executions were outside the day's trading range. The Pittsburgh desk executed more market and non-market trades than any other internal contract type, and cost a total of about 24 basis points, or \$22.5 million. The Pittsburgh treasury desk's executions are problematic and suggest poor transaction controls.

## **Negotiated executions**

SBA's investment managers may negotiate execution orders directly with the London and Pittsburgh desks instead of routing through BNY Mellon's custody system for non-negotiated execution. We would expect these negotiated contract rates to realize better execution than non-negotiated orders. Overall, negotiated custodian executions realized about \$270,000 in excess benefit, or 0.2 basis points. Negotiated custodian executions performed as expected, with less than 2% of all trades executed outside the day's trading range and about half of these being at a disadvantageous rates.

Table 3.3 All internal, negotiated executions by trade size (Contract Types L, X)

## Internal contract type L

Contract type L represents FX executions negotiated directly with BNY Mellon's London treasury desk. The London desk executed more than 3,500 executions through this contract type for SBA, representing about \$3.4 billion. Overall, the direct orders with the London desk realized more than \$486,000 in excess benefit, or about 1.4 basis points. The desk executed all trade-sizes as expected, with only micro-sized trades realizing a loss: 0.5 basis points of excess cost.

Chart 3.7 All internal contract type L trades by value

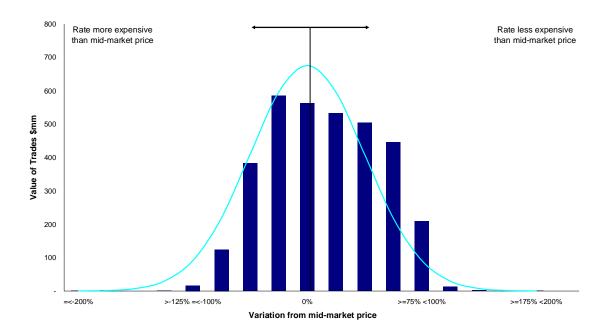

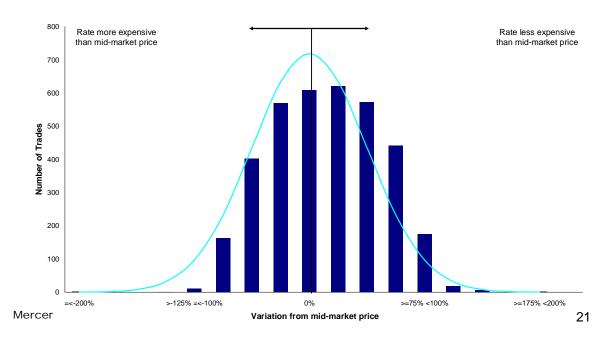

Chart 3.8 All internal contract type L trades by number

## Internal contract type X

Contract type X represents FX orders negotiated directly with BNY Mellon's Pittsburgh desk. The desk handled about 20,000 negotiated executions for SBA, representing about \$10.5 billion traded. In total, contract type X executions realized about \$216,000 in excess costs, or about 0.2 basis points. Overall, the Pittsburgh desk executed the orders well, with about 1% being executed outside the day's trading range. Micro-sized trades gained about 3 basis points, or about \$217,000.

Chart 3.9 All internal contract type X trades by value

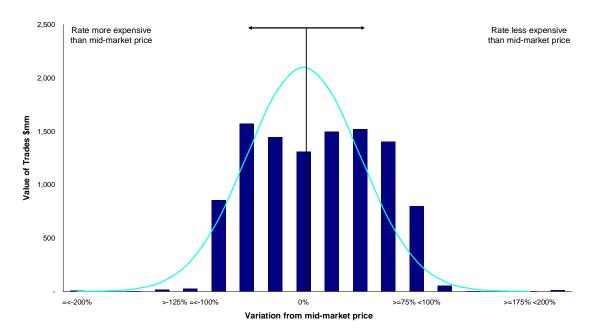

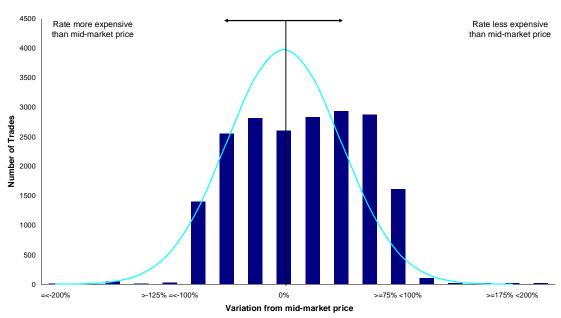

Chart 3.10 All internal contract type X trades by number

### Sub-custodian executions

## Internal contract type I

Contract type I trades represent executions by BNY Mellon's sub-custodians. These are non-negotiated rates where market convention or government rules require local market pricing. About 99% of all contract type I executions involve secondary currencies and about 32% contain SBA's restricted currencies. Overall, the sub-custodians realized excess costs of about 4.9 basis points, or \$1.2 million. We expect secondary currencies to deviate more than reserve currencies, and thus these executions are not surprising, but still somewhat more expensive than we would expect. Only 48% of sub-custodian executions were within the day's trading range. Regardless of currency type, nearly all executions should be within the day's trading range; SBA should discuss these results with BNY Mellon.

Table 3.4 All non-negotiated, sub-custodian executions by trade size (Contract Type I)

|                                      |           | Non-         |         |         |

#### External trade execution

## External broker executions

## Contract type E

SBA's investment managers may execute FX trades with any external broker; for this reason, we consider all external broker executions as negotiated rates whether the investment manager actively or passively negotiates with the broker. BNY Mellon records all external trade executions as contract type E.

Overall, external brokers realized an excess benefit of 2.6 basis points, or \$6.1 million. External brokers executed less than 2% of all trades outside the day's trading range, and more than half of all executions were advantageous. The external brokers realized excess benefits across all trade-sizes. Only cross trades realized excess costs, which accumulated to about \$278,000, or less than 1 basis point.

Table 3.5 External executions by trade size (contract type E)

|                                      |            | Non-       |           |         |

# Trading period analysis

For the period under review, the SBA's foreign equity asset class grew from approximately \$16 billion to almost \$21 billion. During this period, the SBA added to its international equity exposure and consequently hired nine investment managers in October 2007 to boost exposure to international small-cap stocks. The addition of these nine managers increased the volume of FX transactions needed for trade settlement and the repatriation of dividends and other income items. In addition, the SBA's exposure to emerging markets increased as emerging markets grew to represent a larger proportion of the equity asset class allocation. FX executions in several emerging markets are subject to government or market restrictions that tend to result in higher FX execution costs.

The frequency of FX execution has increased each full-year since 2006, but execution type has varied as shown in Table 4.1. External brokers were the best performing contract type in each full year, but use of external brokers has decreased from 42% in 2006 to 19% in 2009. Internal, non-negotiated executions were SBA's worst performing contract type in each measurement period except 2010, which has partial year results. SBA's investment managers have increased their use of internal, non-negotiated executions each full year, from 33% in 2006 to 54% in 2009. The investment managers' use of internal, negotiated rates has remained around 25% each full year.

The first five-months of 2010 show a trend reversal that may reflect SBA's recent efforts to alter investment manager behavior: investment managers have increased their use of external executions to 32%, while decreasing internal, non-negotiated executions from 54% to 42%.

Table 4.1 Summary table, all spot executions by trade year

<sup>&</sup>lt;sup>7</sup> Years 2005 and 2010 are partial years; specifically, 2005 covers from 1 July 2005 and 2010 covers until 31 May 2010.

# Trading year 2005<sup>8</sup>

In 2005, SBA realized about \$1.2 million in excess trading costs, or about 3.8 basis points. External executions comprised about 42% of all executions by number and realized 1.5 basis points in excess benefits. Internal, non-negotiated executions were 26% of all executions and realized 21.2 basis points of excess costs. Internal negotiated and sub-custodian executions realized 1.9 basis points excess costs and 13.9 basis points of excess costs, respectively.

Mercer 30

\_

In 2006, SBA realized about \$1.8 million in excess trading costs, or about 2.5 basis points. External executions comprised about 34% of all executions by number and realized 0.3 basis points in excess benefits. Internal, non-negotiated executions were 33% of all executions and realized 17.9 basis points of excess costs. Internal negotiated and sub-custodian executions realized 0.8 basis points of excess costs and 6.6 basis points of excess costs, respectively.

Chart 4.3 All 2006 spot trades by value

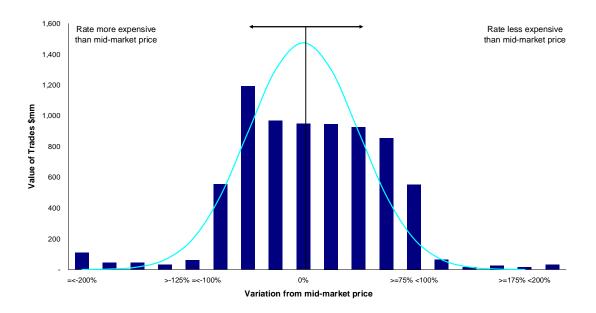

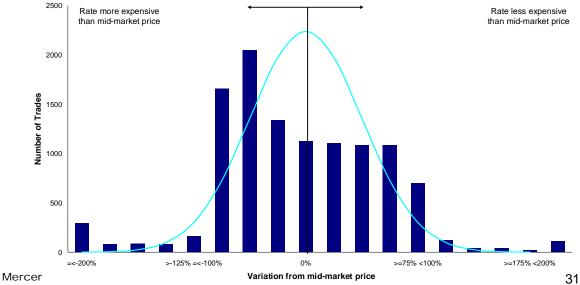

Chart 4.4 All 2006 spot trades by number

In 2007, SBA realized about \$634,000 in excess trading costs, or about 0.7 basis points. Internal, non-negotiated execution became the most frequently used execution contract type at 38% of all executions. These executions realized about 14.2 basis points of excess costs. External executions comprised about 30% of all executions by number and realized 1.8 basis points in excess benefits. Internal negotiated executions realized about 0.9 basis points of excess benefit, while sub-custodian executions realized 0.1 basis points excess costs.

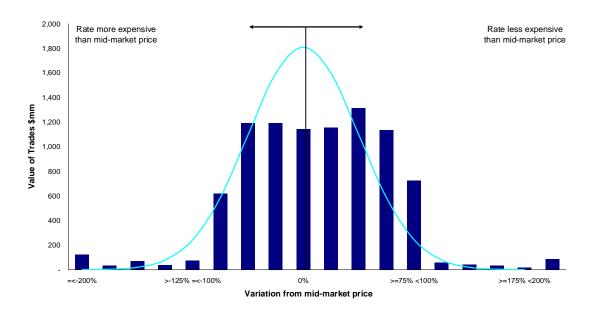

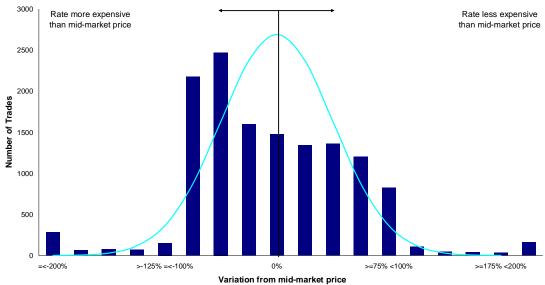

Chart 4.6 All 2007 spot trades by number

Variation from mid-market price

Mercer 32

In 2008, SBA realized about \$7.9 million in excess trading costs, or about 5.4 basis points. Internal, non-negotiated executions comprised about 50% of all executions by number and realized 26.6 basis points in excess costs. Internal, negotiated executions comprised about 26% of all executions and realized about 0.6 basis points in excess benefit. External executions dropped to 21% of all executions and realized 0.7 basis points of excess benefit. Sub-custodian executions realized 2.6 basis points of excess costs during the year.

Chart 4.7 All 2008 spot trades by value

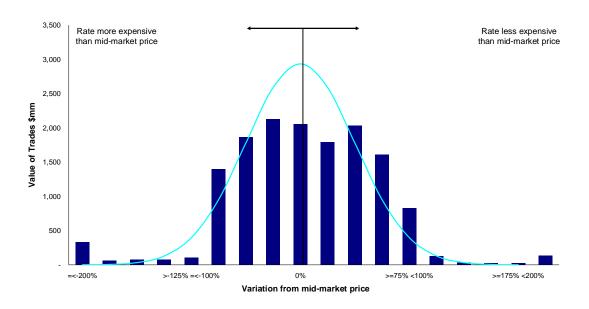

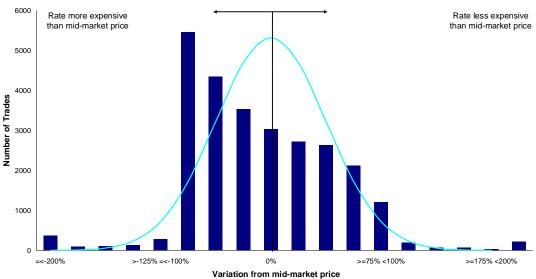

Chart 4.8 All 2008 spot trades by number

In 2009, SBA realized about \$10.0 million in excess trading costs, or about 8.3 basis points. Internal, non-negotiated executions increased to 54% of all executions by number and realized 31.9 basis points in excess costs. Internal, negotiated executions comprised about 25% of all executions and realized about 0.1 basis points in excess benefit. External executions dropped to 19% of all executions and realized 5.6 basis points of excess benefit. Sub-custodian executions realized 30.4 basis points of excess costs, but were only 2% of all 2009 executions.

Chart 4.9 All 2009 spot trades by value

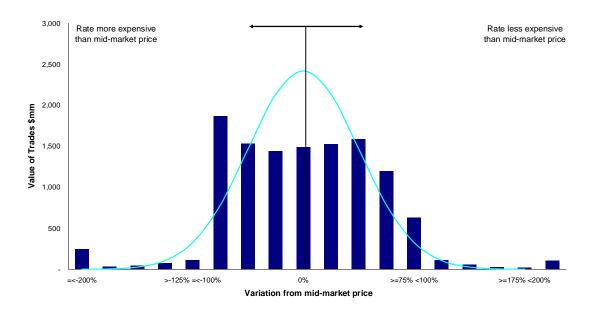

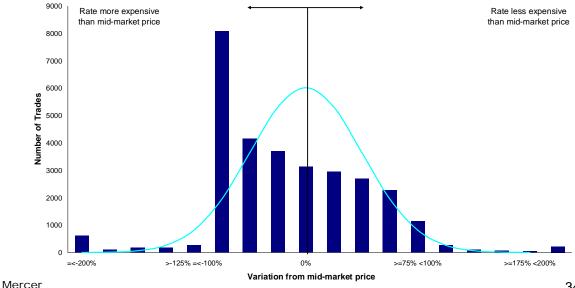

Chart 4.10 All 2009 spot trades by number

34

During the first five-months of 2010, SBA realized about \$11,000 in excess trading benefits, or less than one-tenth of a basis point. Internal, non-negotiated executions decreased to 42%, but remained the most frequently used contract type and realized 20.5 basis points of excess costs. External execution increased to 32% of all trades and realized 9.7 basis points of excess benefit. Internal negotiated executions were 25% of all executions and realized 1.1 basis points of excess benefit. Sub-custodian executions realized 40.7 basis points of excess costs, but were less than 2% of all 2010 executions.

5

# Trade size analysis

SBA's investment managers executed approximately \$50.4 billion in spot executions during the review period at an excess cost of 4.3 basis points. Market-sized executions, which represent \$41.6 billion, but only 22% of spot trades by number, incurred an excess cost of \$10.7 million, or 2.6 basis points. Eight-percent of market trades were outside the day's trading range, which is a larger percentage than expected from organizations with effective trading controls.

Micro-trades, which accounted for \$4.1 million in total costs and 54% of spot trades by number, were problematic. While 6% of micro-trades were outside the day's trading range, micro-trades accumulated more than 16 basis points of excess cost. Mercer Sentinel expects BNY Mellon to execute nearly 100% of trades within the day's posted market prices, regardless of trade size.

Table 5.1 All spot executions by trade size

|                                      |            |            | Non-      | _         |
|--------------------------------------|------------|------------|-----------|-----------|
|                                      | Total      | Market     | Market    | Micro     |
| Total value of all trades, \$000's   | 50,377,952 | 41,559,006 | 6,250,962 | 2,567,984 |
| Excess benefit (+)/cost (-), \$000's | (21,578)   | (10,667)   | (6,837)   | (4,074)   |
| Benefit (+)/cost (-), bps            | (4.3)      | (2.6)      | (10.9)    | (15.9)    |
| Total number of trades               | 96,308     | 21,618     | 22,278    | 52,412    |
| Number with excess costs             | 62,134     | 11,663     | 13,642    | 36,829    |
| Percentage disadvantageous by number | 65%        | 54%        | 61%       | 70%       |
| Value of disadvantageous, \$000's    | 27,192,980 | 21,721,554 | 3,783,687 | 1,687,739 |
| Percentage disadvantageous by value  | 54%        | 52%        | 61%       | 66%       |
| % within days range (by value)       | 94%        | 94%        | 92%       | 94%       |
| % within days range (by number)      | 93%        | 92%        | 92%       | 94%       |

### Market trades

Market-sized executions contributed about \$10.7 million in excess trading costs, which is about 2.6 basis points of total volume traded. Market-sized trades are the most efficient trade size in FX markets and should realize minimal excess costs with nearly all trades executing within the day's trading range. Overall, 8% of market-sized trades executed above the day's highest price or below the day's lowest price. Internal contract executions contributed about 92% of the 1,600+ executions outside the day's trading range and accumulated more about \$16.3 million in excess costs, or 8.0 basis points. SBA should question BNY Mellon on its market-sized execution controls, as BNY Mellon should execute almost all trades within the day's trading range. External executions contributed \$5.6 million in excess benefit, or about 2.7 basis points.

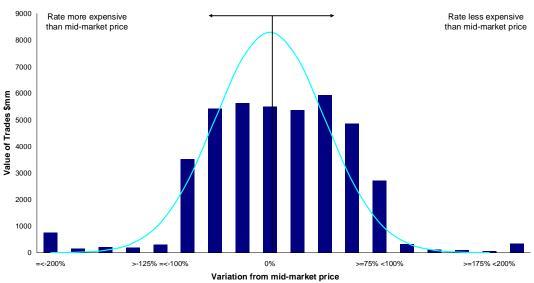

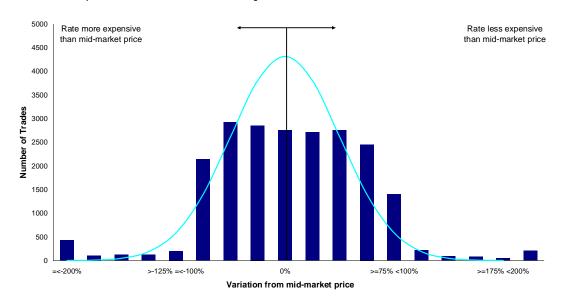

Chart 5.1 All spot market sized trades by value

### Non-market trades

Non-market trades are less efficient to trade than market-sized orders, and subsequently may incur greater excess costs. SBA realized \$6.8 million in excess costs from non-market sized executions, or about 10.9 basis points. About 8% of executions were outside the day's trading range, which is excessive. Internal execution types accounted for about 92% of the 1,700+ executions outside the day's trading range, and accumulated more than \$7.2 million in excess trading costs. Non-market sized executions in external contract types benefited by about \$397,000, or about 2 basis points.

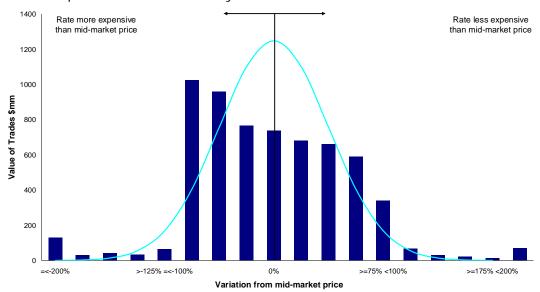

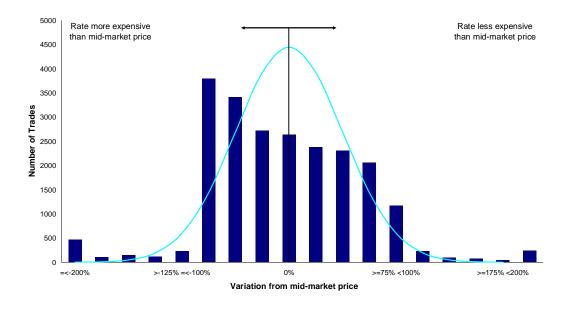

Chart 5.3 All spot non-market trades by value

### Micro-trades

Micro-sized trades are frequently problematic, as the size is inefficient to trade within the FX markets. SBA incurred about \$4.1 million in excess costs, or about 15.9 basis points of traded value; more than 6% of all micro-sized trades were executed outside the day's trading range, which is greater than our 2% expectation. BNY Mellon executions contributed more than \$4.1 million of excess cost, or about 20.2 basis points. These internal contract types also accounted for more than 95% of the 3,300+ trades executed outside the day's trading range. SBA should discuss these results with BNY Mellon. In our experience, poor custodian execution often derives from their auto-repatriation process. SBA may wish to pay particular attention to BNY Mellon's auto-repatriation controls and to establish benchmark criteria for these trades.

External micro-sized executions added \$69,000 in excess benefit, or 1.3 basis points, and executed about 2% of trades outside the day's trading range, which is within our expectations for the trade size.

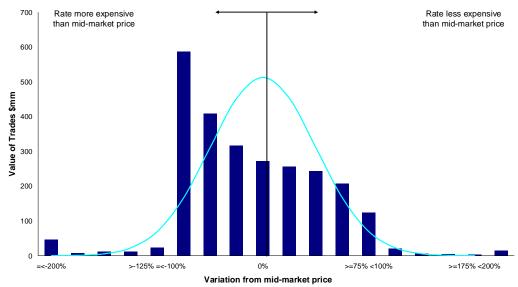

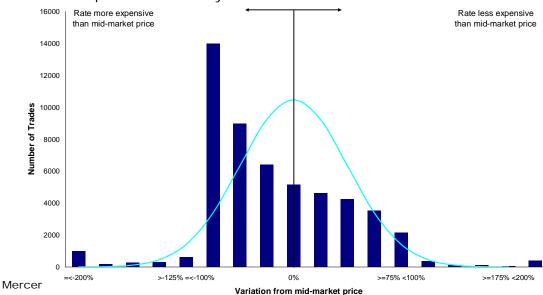

Chart 5.6 All spot micro-trades by number

6

# Currency pair analysis

The table below shows the ten most frequently traded currency pairs across spot trades. These ten currency pairs represent 77% of all trades by frequency and 74% by volume traded. Of the top ten currency pairs, only JPY and AUD executions resulted in excess benefits. South Korean won (KRW) and Brazilian real (BRL) executions were excessively poor and require discussion with BNY Mellon regarding non-negotiated executions.

Table 6.1 Top 10 frequently traded spot currency pairs

| Total             | 73,955         | 37,188,502                        | 66%                      | 96%  | (16,714)  | (4.5)  |

### Euro

The euro is a free-floating, reserve currency used by 16 of 27 countries in the European Union, including Austria, Belgium, Cyprus, Finland, France, Germany, Greece, Ireland, Italy, Luxemburg, Malta, the Netherlands, Portugal, Slovakia, Slovenia, and Spain. The currency market for the euro is liquid.

SBA's investment managers traded about \$12.0 billion in euro currency, and incurred \$3.7 million in excess costs, or 3.1 basis points of traded value. About 1% of these executions were outside the day's trading range, which is within our expectations. Sixty percent of all executions were euro purchases (by number), which incurred 4.4 basis points in excess costs. Micro-sized trades were particularly costly at 19.5 basis points of traded value, or \$1.1 million.

BNY Mellon, non-negotiated contract types executed about 52% of all euro trades, and cost more than 24.7 basis points. This cost is excessive for such a liquid currency; BNY Mellon should explain the reason for incurring such high costs. Only internal negotiated and external contract types accumulated excess benefits: 0.1 basis points and 2.3 basis points, respectively.

Table 6.2 All spot trades in USD/EUR currency pairs

|                                      | Total      | Buy        | Sell      |

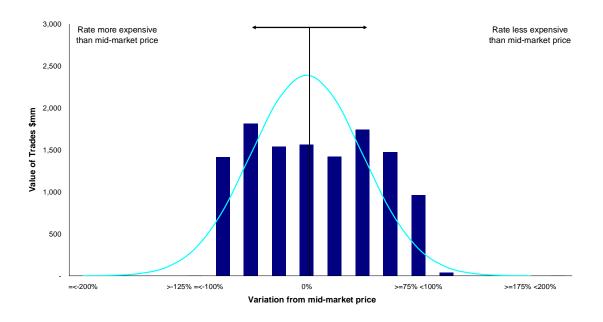

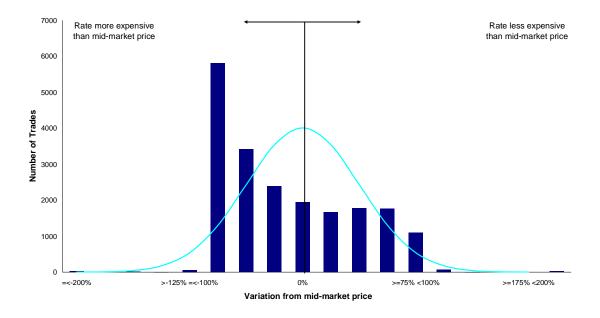

Chart 6.2 All spot trades by number in USD/EUR currency pairs

### Japanese yen

The Japanese yen (JPY) is a free-floating, reserve currency with no government restrictions. The currency market for JPY is liquid.

SBA's investment managers traded more about \$6.2 billion in yen currency, and gained about \$554,000 in excess benefit, or 0.9 basis points of traded value. About 1% of these executions were outside the day's trading range, which is within our expectations. Forty-one percent of all executions were yen sales, which accumulated about 1.4 basis points in excess benefits. Micro-sized trades, however, were particularly costly at 9.5 basis points of traded value, or about \$328,000.

BNY Mellon, non-negotiated contract types executed about 37% of all yen trades, and cost more than 22.2 basis points. All other aggregated contract types gained excess benefits. Internal negotiated accounted for 34% of all trades and gained 1.8 basis points. External executions were about 29% of all yen trades and gained 5.7 basis points of excess benefits.

Table 6.3 All spot trades in JPY/USD currency pairs

|                                      | Total     | Buy        | Sell      |

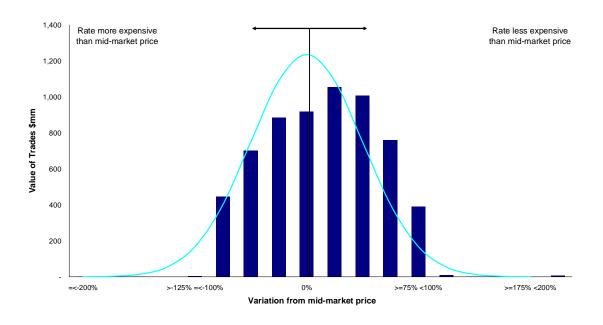

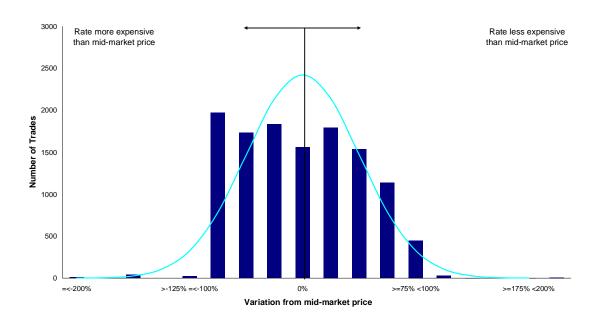

Chart 6.4 All spot trades by number in JPY/USD currency pairs

# British pound sterling

The British pound sterling (GBP or pound) is a free-floating, reserve currency with no government restrictions. The GBP currency market is liquid.

SBA's investment managers traded more about \$6.0 billion in pound currency, and had about \$2.0 million in excess costs, or 3.3 basis points of traded value. About 1% of these executions were outside the day's trading range, which is within our expectations. Fifty-six percent of all executions were pound purchases, which accumulated about 4.0 basis points in excess costs. Micro-sized trades, however, were particularly costly at 20.0 basis points of traded value, or about \$725,000.

BNY Mellon, non-negotiated contract types executed about 53% of all pound trades, and cost more than 22.7 basis points. This cost is excessive for such a liquid and widely available currency; BNY Mellon should explain the reason for incurring such high costs. Only external contract types accumulated excess benefits: 3.7 basis points.

Table 6.4 All spot trades in GBP/USD currency pairs

|                                      | Total     | Buy        | Sell      |

#### Canadian dollar

The Canadian dollar (CAD) is a free-floating, reserve currency with no government restrictions. The CAD currency market is liquid.

SBA's investment managers traded more about \$1.9 billion in CAD, and had about \$1.0 million in excess costs, or 5.3 basis points of traded value. About 2% of these executions were outside the day's trading range, which is within our expectations. Forty-one percent of all executions were CAD sells, which accumulated about 7.9 basis points in excess costs. Micro-sized trades, however, were particularly costly at 19.1 basis points of traded value, or about \$383,000.

BNY Mellon, non-negotiated contract types executed about 57% of all CAD trades, and cost more than 40.8 basis points – or \$1.9 million – in excess costs. This cost is excessive for such a liquid currency; BNY Mellon should explain the reason for incurring such high costs. Only internal negotiated and external contract types accumulated excess benefits: 6.3 basis points in excess benefits for both contract types.

Table 6.5 All spot trades in CAD/USD currency pairs

|                                      | Total     | Buy        | Sell    |

# Hong Kong dollar

The Hong Kong dollar (HKD) is a USD-pegged, secondary currency. Since 2005, the HKD has been pegged to the USD to trade within HKD 7.75 to HKD 7.85. The HKD currency market is liquid.

SBA's investment managers traded more about \$2.8 billion in HKD, and had about \$43,000 in excess costs, or 0.2 basis points of traded value, which is well within our expectations for the currency. About 9% of these executions were outside the day's trading range, which is unexpected for HKD. Both internal and external contract types realized about 9% of total executions outside the day's trading range. Of the internal executions, about 96% were associated with the Pittsburgh trading desk (contract types T and X). Possible explanations for the out-of-day-range results include: 1) an accounting time-zone entry difference between the Hong Kong and Pittsburgh locations, or 2) a systemic control issue at the Pittsburgh treasury desk. In any case, BNY Mellon should investigate and explain the reason for the excessive trades outside the day's range.

Fifty-three percent of all HKD executions were purchases, which accumulated about 0.1 basis points in excess costs. Even micro-sized trades were within a reasonable pricing range: 0.6 basis points of excess cost. BNY Mellon, non-negotiated contract types executed about 39% of all HKD trades, and cost 1.2 basis points – or about \$34,000 – in excess costs. This cost is reasonable for HKD. Only external contract types accumulated excess benefits: 0.2 basis points.

Table 6.6 All spot trades in HKD/USD currency pairs

|                                      | Total     | Buy        | Sell      |
|--------------------------------------|-----------|------------|-----------|
| Total value of all trades, \$000's   | 2,811,279 | 1,259,433  | 1,551,845 |
| Excess benefit (+)/cost (-), \$000's | (43)      | (17)       | (26)      |
| Benefit (+)/cost (-), bps            | (0.2)     | (0.1)      | (0.2)     |

### Australian dollar

The Australian dollar (AUD) is a free-floating, secondary currency with no government restrictions. The AUD market is liquid.

SBA's investment managers traded more about \$1.3 billion in AUD, and had about \$627,000 in excess benefits, or 4.8 basis points of traded value. About 3% of these executions were outside the day's trading range, which is slightly more than our expectations. Sixty-one percent of all executions were AUD purchases, which accumulated about 5.2 basis points in excess benefits. Micro-sized trades, however, were costly at 9.7 basis points of traded value, or about \$114,000.

External brokers executed the greatest portion of AUD trades: about 42% by frequency. These executions resulted in about 12.8 basis points of excess benefit, or \$1.1 million. All internal contract types realized excess costs. BNY Mellon, non-negotiated contract types executed about 38% of all AUD trades, and cost more than 25.8 basis points – or \$384,000 – in excess costs. These costs are excessive for such a liquid currency; BNY Mellon should explain the reason for incurring such high costs.

Table 6.7 All spot trades in AUD/USD currency pairs

|                                      | Total     | Buy        | Sell    |

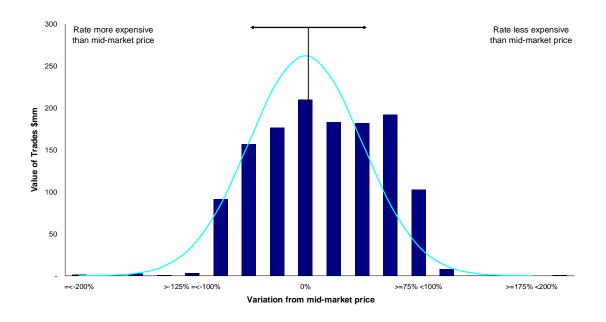

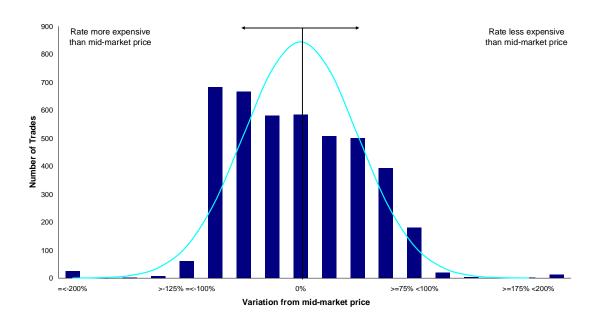

Chart 6.12 All spot trades by number in AUD/USD currency pairs

#### Swiss franc

The Swiss franc (CHF) is a free-floating, reserve currency with no government restrictions. The CHF currency market is liquid.

SBA's investment managers traded more about \$2.6 billion in CHF, and had about \$1.6 million in excess costs, or 6.2 basis points of traded value. About 1% of these executions were outside the day's trading range, which is within our expectations. Forty percent of all executions were CHF sells, which accumulated about 6.6 basis points in excess costs. Micro-sized trades were particularly costly at 23.5 basis points of traded value, or about \$233,000.

BNY Mellon, non-negotiated contract types executed about 49% of all CHF trades, and incurred 27.4 basis points – or \$1.3 million – in excess costs. This cost is excessive for such a liquid currency; BNY Mellon should explain the reason for incurring such high costs. Only external contract types were within a reasonable cost range: about 0.7 basis points, or \$90,000, of excess costs.

Table 6.8 All trades by all managers in CHF/USD currency pairs

|                                      | Total     | Buy        | Sell      |
|--------------------------------------|-----------|------------|-----------|
| Total value of all trades, \$000's   | 2,608,889 | 1,318,573  | 1,290,316 |
| Excess benefit (+)/cost (-), \$000's | (1,606)   | (756)      | (850)     |

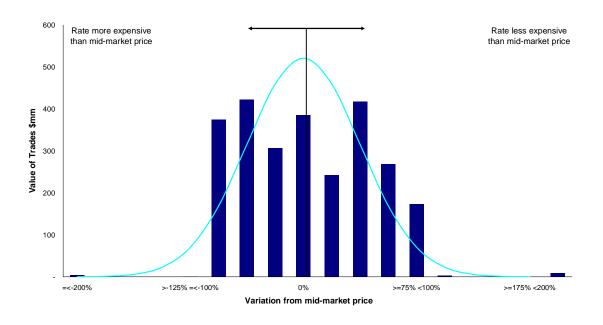

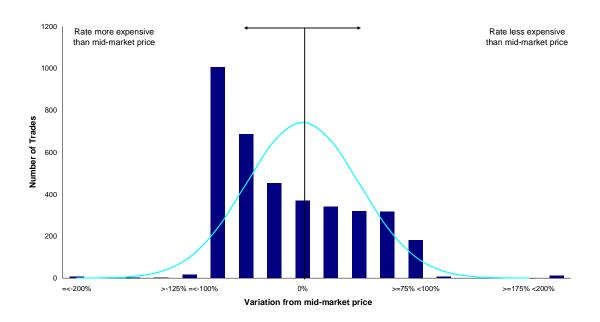

Chart 6.14 All trades by number for all managers in CHF/USD currency pairs

#### South Korean won

The South Korean won (KRW) is a managed currency with government restrictions. All FX associated with security transactions must be executed onshore through a registered local dealer. A segregated offshore market exists, but purchases are not freely convertible into South Korea for investment purposes.

SBA's investment managers traded more about \$2.5 billion in won, and had about \$4.3 million in excess costs, or 16.6 basis points of traded value. About 46% of these executions were outside the day's trading range, which is widely outside our 2% expectation for the currency – even with restrictions. Forty-four percent of all executions were won sells, which accumulated about 23.2 basis points in excess costs. All trade sizes were costly; micro-sized trades were particularly costly at 30.6 basis points of traded value, or about \$191,000.

BNY Mellon sub-custodian, non-negotiated contract types executed about 61% of all won trades, but cost only 3.6 basis points – or \$593,000 – in excess costs, which is reasonable given the local restrictions. BNY Mellon, non-negotiated contract types accumulated the majority of excess costs: about 43.0 basis points, or \$3.5 million. This cost is excessive for the currency; BNY Mellon should explain the reason for incurring such high costs from non-negotiated executions. Internal, negotiated and external contract types lacked sufficient records to draw statistically significant conclusions about their results.

Table 6.9 All spot trades in KRW/USD currency pairs

|                                      | Total     | Buy        | Sell      |
|--------------------------------------|-----------|------------|-----------|
| Total value of all trades, \$000's   | 2,491,526 | 1,207,786  | 1,283,740 |
| Excess benefit (+)/cost (-), \$000's | (4,133)   | (1,155)    | (2,978)   |

#### Brazilian real

The Brazilian real (BRL) is a managed floating currency, with government restrictions limiting the volatility of the currency. All FX associated with security transactions must be executed onshore through a registered local dealer. A segregated offshore market does not exist.

SBA's investment managers traded more about \$1.2 billion in real, and had about \$5.3 million in excess costs, or 42.9 basis points of traded value. About 9% of all executions were outside the day's trading range, which is greater than our expectation. Forty-eight percent of all executions were real sells, which accumulated about 47.6 basis points in excess costs. All trade sizes had excessive costs, incurring more than 42 basis points of cost in each trade-size category.

BNY Mellon, non-negotiated contract types executed about 95% of all real trades, and cost more than 44.3 basis points – or \$5.4 million – in excess costs. This cost is excessive for such a currency; BNY Mellon should explain the reason for incurring such high costs. In total, internal, negotiated trades accumulated \$54,000 in excess benefit, or about 64.3 basis points against traded value. Sub-custodian and external contract types lacked sufficient records to draw statistically significant conclusions.

Table 6.10 All spot trades in BRL/USD currency pairs

|                                      | Total     | Buy        | Sell    |

# Singaporean dollar

The Singapore dollar (SGD) is a free-floating, secondary currency with no government restrictions. The currency market for SGD is liquid.

SBA's investment managers traded about \$610 million in SGD and had about \$132,000 in excess costs, or 2.2 basis points of traded value. About 2% of these executions were outside the day's trading range, which is within our expectations. Sixty-one percent of all executions were SGD purchases, which accumulated about 2.9 basis points in excess costs. Non-market sized trades were the most costly at 4.9 basis points, or \$156,000, which is reasonable for the currency.

Non-negotiated contract types executed about 43% of all SGD trades, and cost about 7.8 basis points – or \$132,000 – in excess costs. This cost is somewhat high for the currency. Only external contract types accumulated excess benefits: 0.1 basis points in excess benefits, or \$3,000.

Table 6.11 All spot trades in SGD/USD currency pairs

|                                      | Total   | Buy        | Sell    |

7

# Forward execution analysis

Forward executions realized about \$519,000, or about 0.4 basis points, of excess cost. As consistent with spot trades, internal contract types contributed most to excess costs: about \$928,000, or 4.4 basis points. In contrast, external contract types contributed excess benefits: about \$408,000, or 0.4 basis points. External trading brokers executed 98% of executions within the day's trading range, but only 92% of BNY Mellon's forward executions were inside the day's trading range, suggesting that BNY Mellon lacks effective forward execution controls.

Table 7.1 All forward executions by trade size

|                                      |            |            | Non-    |         |

### Forward market trades

Market-sized forward executions resulted in excess benefits of about \$90,000, or about 0.1 basis points against \$12.2 billion traded. Overall, 7% of forward, market-sized trades were executed outside the day's traded range. Internal contract executions contributed 74% of the total 115 market-sized forward executions outside the day's trading range. External negotiated contracts executed about 55% of all forward market trades, and realized about 0.4 basis points of excess benefit. Internal, negotiated executed about 32% of all forward, market-sized trades, and realized about 0.3 basis points of excess costs. Internal, non-negotiated forward rates were about 10% of all forward executions and realized 17.0 basis points of excess cost, or \$344,000.

#### Forward non-market trades

SBA realized \$396,000 in excess costs from forward, non-market sized executions, or about 9.9 basis points against \$399 million traded. About 7% of forward, non-market sized executions were outside the day's trading range. Internal contract executions contributed about 93% of forward, non-market sized executions outside the day's interpolated trading range.

External negotiated contracts executed about 34% of all forward, non-market trades, and realized about 0.5 basis points of excess cost. About 1% of these external, non-market forward executions were outside the day's trading range. Internal, negotiated executed about 34% of all forward, non-market sized trades, as well, and realized about 3.4 basis points of excess costs. Internal, non-negotiated forward rates were about 28% of all forward executions and realized 33.0 basis points of excess cost, or \$353,000.

Mercer 63

\_

<sup>&</sup>lt;sup>10</sup> BNY Mellon should comment on its forward execution controls; however, since we interpolate a day's range from near and far contracts (see Appendix for further details), SBA should bear in mind the percentage outside the day's range may be higher or lower than our estimate for all forward contract types.

Chart 7.4 All forward non-market sized trades by number

### Forward micro-trades

Micro-sized, forward executions resulted in excess costs of about \$213,000, or 13.2 basis points against \$161 million traded. Overall, 5% of forward, micro-sized trades executed outside the day's traded range. Internal contract executions contributed about 96% of all forward, micro-sized executions outside the day's trading range. Internal, negotiated contracts executed about 40% of all forward, micro-sized trades, and realized about 1.7 basis points of excess benefit, or \$11,000. Internal, non-negotiated contracts executed about 33% of all forward, market-sized trades, and realized about 45.7 basis points of excess costs, which BNY should explain. External, negotiated forward rates were about 24% of all forward, micro executions and realized 0.1 basis points of excess cost.

# Foreign exchange transaction cost analysis methodology

There are two approaches to currency transaction cost analysis, depending on whether time-stamped trading data is available.

### Time-stamped data

Where time of trade information is provided, a comparison is made between the actual price achieved and market prices available at or close to that time. Mercer Sentinel attains prices across a range of currencies every 15-minutes during market hours via Bloomberg pricing data. In a time-stamped analysis, we compare the traded price to the quoted market rate at the time of the trade, or a rate interpolated between the two nearest quoted prices on either side of the execution time. The results are presented graphically, grouping trades according to their variation from the interpolated rate ("market mid-price"). Effective trading would result in a tight grouping around the market mid-price with a bias to the less expensive side.

Price-makers can legitimately refuse to make general time-stamped data across their books available to third parties. However, custodians, acting as fiduciary agents for their clients, should be able to provide time-stamped trade data specific to the client. While it is common practice, it is poor internal control not to maintain time-stamped information.

# Non time-stamped data

In some cases, custodians do not maintain time-stamped information, while in other cases, time-stamped information is not available on external systems. In such situations, Mercer Sentinel must base FX audit analyses on the intra-day market price ranges: the highest and lowest execution prices during the transaction day. Mercer Sentinel assumes US Eastern Time as the basis for a trading day. For each day, we review the price range and calculate the midpoint from the high offer and low bid. Then, we

compare the actual execution price against the midpoint and daily range to determine its divergence from an anticipated trade during that specific day. For instance, if GBP/USD daily price range was 1.5000 to 1.5100, we calculate the midpoint at 1.5050 (assuming no bid-offer spread). If a manager purchased GBP and sold USD at a rate of 1.5050, Mercer Sentinel considers the trade 0% off market. If the transaction occurs at 1.5060, we consider the difference between the execution and midpoint at 20% off market. In this example, the trade would be more expensive to the client, and thus measured at -20%. Additionally, Mercer Sentinel considers a trade greater than +100% or less than -100% outside the relevant day's relevant price range.

### Estimating excess costs for non-time stamped data

Statistically, relative positions of individual trades provide little information in isolation. For instance, a transaction may lie at the expensive end of its day price range due to the particular execution time in the market and may not necessarily signify an uncompetitive transaction. A reasonably sized sample should distribute executions across the spectrum from -100% to +100%, and coverage to a normal distribution, where the midpoint price is zero. For a normal distribution to hold, one must assume that over time the intra-day pattern of market prices is random in nature and normally distributed. If these assumptions are correct, significant divergences from a normal trade execution distribution<sup>11</sup> over a portfolio of trades suggests that pricing has been systematically disadvantaged or advantaged.

Without adjusting for standard trading costs, such as bid-offer spreads, an FX analysis tends to produce a slight bias towards disadvantageous pricing. FX markets execute on a principal basis, with bid-offer spreads and generally no additional commissions. Bid-offer spreads mean that the price-taker pays for the price-makers services by purchasing at a higher price than it can sell to the price-maker at any particular time; thus, the price taker always incurs a slight disadvantage of the spread cost. Such a bias skews the trade execution distribution negatively, suggesting that the price-taker has received consistently non-competitive pricing.

To account for bid-offer spread, we adjust the rates traded by half the average bid-offer spread to reflect standing trading costs. The size of bid-offer spread adjustments vary among currency pairs, which we expect to be present on a typical competitive market-size trade. We calculate the bid-offer spread adjustment from quantitative historical data, and qualitative market experience.

Certain currency pairs in our analysis for SBA do not have significant bid-offer spread information. As agreed with SBA, we isolated these currencies and make special reference in the report where this absence of information materially affects our analysis.

Mercer 67

\_

<sup>&</sup>lt;sup>11</sup> A normal distribution is symmetrical around the median and the number of observations gradually reduce as one moves away from the median. We would expect the median observation to be close to 0%.

# Trading pattern analysis

BNY Mellon's FX data did not include execution time-stamps, and hence, we have analyzed the data on a day-range basis. Mercer Sentinel considered the general number and value of spot and forward trades analyzed sufficient to make use of the day-range methodology.

While interpreting our report, it is important to bear in mind that Mercer Sentinel evaluated trades based on divergence from the day's market midpoint. Execution on the negative side of the market midpoint incurs a cost to SBA. Execution on the positive side of the market midpoint delivers a benefit to SBA.

For example, during a currency purchase, if we found the trade to be 0% off market, then the trade was executed at the day's midpoint. If the purchase is +100% off the day's midpoint, the buy was executed at the day's low and, therefore, favorable to SBA; and -100% off the day's midpoint indicates a purchase at the day's high and, therefore, unfavorable to SBA.

Appendix D

# Imputed spread assumptions

Mercer Sentinel calculates and imputes a spread assumption specific to each currency pair, as described in Appendix A. We do this to adjust for the normal cost of executing in a market so that we can identify the "excess" costs/benefits associated with FX trading. We derive the appropriate spread assumption by analyzing historical spread rates and adjusting where appropriate.

A de minimis portion of SBA's currency pairs did not have sufficient history or data to model an appropriate spread statistically. As a result, 742 executions in our analysis did not have imputed spread assumptions. These executions represented a trade volume of \$156 million and realized about \$444,000 of excess costs, assuming no normal spread. A majority of the securities were secondary and restricted currencies, which generally have a higher cost of executing. Assuming a spread of 8 pips<sup>13</sup> for these 742 executions, the total excess cost decreases to about \$334,000. It should be noted that adding this 8 pip spread assumption reduces overall excess costs reported by about \$110,000.

The following tables present 1) results for the 742 executions without assumed spreads, by contract type and by year (Tables A3 and A4), and 2) the spreads assumed for each currency pair (Table A5).

<sup>&</sup>lt;sup>13</sup> "Pips" are the smallest possible increments of price change in currency trading. They generally represent a .0001 change in the currency denomination.

Table A3 Aggregate execution profile by contract type for currency pairs with no spread assumptions only
